Computation Aspect

## Density Derivatives

- Consider the problem of estimating the  $r$ th derivative of the density

$$f^{(r)}(x) = \frac{d^r}{dx^r} f(x)$$

- Since the kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{X_i - x}{h}\right) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - X_i}{h}\right)$$

- A natural estimator is found by taking derivatives of the kernel density estimator. This takes the form

$$\hat{f}_h^{(r)}(x) = \frac{1}{nh^{r+1}} \sum_{i=1}^n K^{(r)}\left(\frac{x - X_i}{h}\right)$$

where  $K^{(r)}$  is the  $r$ th order derivative of kernel  $K$ .

- This estimator only makes sense if  $K^{(r)}(x)$  exists and is non-zero.
- Suppose the kernel  $K$  satisfy the previous assumptions, with additionally,  $K^{(s)}(\infty) = 0, K^{(s)}(-\infty) = 0, s = 0, 1, 2, \dots, r$ .
- Notice that  $K^{(r)}(\frac{X_i - x}{h}), i = 1, 2, \dots, n$  are i.i.d variables,

$$\begin{aligned}
 Ef_h^{(r)}(x) &= \frac{1}{h^{r+1}} EK^{(r)}\left(\frac{x - X_1}{h}\right) \\
 &= \frac{1}{h^r} \int K^{(r)}(u) f(x - uh) du = \frac{1}{h^r} \int f(x - uh) dK^{(r-1)}(u) \\
 &= \frac{1}{h^r} K^{(r-1)}(u) f(x - uh) \Big|_{-\infty}^{+\infty} - \frac{1}{h^r} \int K^{(r-1)}(u) df(x - uh) \\
 &= \frac{1}{h^{r-1}} \int K^{(r-1)}(u) f'(x - uh) du \\
 &= \frac{1}{h^{r-1}} \int K^{(r-1)}\left(\frac{x - z}{h}\right) f'(z) dz
 \end{aligned}$$

Repeating this a total of  $r$  times, we obtain

$$\begin{aligned} E f_h^{(r)}(x) &= \frac{1}{h} \int K\left(\frac{x-z}{h}\right) f^{(r)}(z) dz \\ &= \frac{1}{h} \int K(u) f^{(r)}(x - uh) du \\ &= \frac{1}{h} \int K(u) [f^{(r)}(x) - f^{(r+1)}(x)uh + \frac{1}{2} f^{(r+2)}(x)u^2 h^2 + o(h^2)] du \\ &= f^{(r)}(x) + \frac{1}{2} f^{(r+2)}(x) \kappa_{21} h^2 + o(h^2) \end{aligned}$$

Thus, the bias of  $\hat{f}_h^{(r)}(x)$  is

$$\text{bias}(\hat{f}_h^{(r)}(x)) = \frac{1}{2} f^{(r+2)}(x) \kappa_{21} h^2 + o(h^2)$$

For the variance, we find

$$\begin{aligned} \text{Var}(f_h^{(r)}(x)) &= \frac{1}{n} \text{Var}\left(\frac{1}{h^{r+1}} K^{(r)}\left(\frac{x - X_1}{h}\right)\right) \\ &= \frac{1}{n} E\left[\frac{1}{h^{r+1}} K^{(r)}\left(\frac{x - X_1}{h}\right)\right]^2 - \frac{1}{n} \left\{ \frac{1}{h^{r+1}} E K^{(r)}\left(\frac{x - X_1}{h}\right) \right\}^2 \\ &= I_1 + I_2, \end{aligned}$$

where the first term  $I_1$ ,

$$\begin{aligned} I_1 &= \frac{1}{n} E\left[\frac{1}{h^{r+1}} K^{(r)}\left(\frac{x - X_1}{h}\right)\right]^2 = \frac{1}{nh^{2(r+1)}} \int [K^{(r)}(u)]^2 f(x - uh) du \\ &= \frac{f(x)}{nh^{2r+1}} \int [K^{(r)}(u)]^2 du + o\left(\frac{1}{nh^{2r+1}}\right). \end{aligned}$$

Since

$$\begin{aligned} I_2 &= \frac{1}{n} \left\{ \frac{1}{h^{r+1}} E K^{(r)}\left(\frac{x - X_1}{h}\right) \right\}^2 \\ &= \frac{1}{n} [f^{(r)}(x) + \frac{1}{2} f^{(r+1)}(x) \kappa_{21} h^2 + o(h^2)] \\ &= o\left(\frac{1}{nh^{2r+1}}\right). \end{aligned}$$

We have

$$\text{Var}[(f_h^{(r)}(x))] = \frac{f(x)}{nh^{2r+1}} \int [K^{(r)}(u)]^2 du + o\left(\frac{1}{nh^{2r+1}}\right)$$

and

$$\begin{aligned} \text{MSE}[(f_h^{(r)}(x))] &= \frac{f(x)}{nh^{2r+1}} \int [K^{(r)}(u)]^2 du + \frac{1}{4} [f^{(r+2)}(x)]^2 \kappa_{21}^2 h^4 \\ &\quad + o\left(\frac{1}{nh^{2r+1}}\right) + o(h^4) \end{aligned}$$

Therefore, the MISE is

$$\begin{aligned} MISE[(f_h^{(r)})(x)] &= \int MSE[(f_h^{(r)})(x)]dx \\ &= \underbrace{\frac{1}{nh^{2r+1}} \int [K^{(r)}(u)]^2 du + \frac{1}{4} \int [f^{(r+2)}(x)]^2 dx \kappa_{21}^2 h^4}_{AMISE_r(h)} \\ &\quad + o\left(\frac{1}{nh^{2r+1}}\right) + o(h^4) \end{aligned}$$

The optimal bandwidth  $h_{opt}$  can be obtained by minimizing AMISE,

$$\begin{aligned} h_{opt} &= \arg \min AMISE_r(h) \\ &= \left[ \frac{(2r+1) \|K^{(r)}\|^2}{\|f^{(r+2)}\|^2 \kappa_{21}^2} \right]^{1/(2r+5)} n^{-1/(2r+5)} \end{aligned}$$

With optimal  $h_{opt}$ , it is easily seen that

$$AMISE_r(h_{opt}) = O(n^{-4/(2r+5)})$$

- $r = 0$ ,  $AMISE_0(h_{opt}) = O(n^{-4/5})$
- $r = 1$ ,  $AMISE_1(h_{opt}) = O(n^{-4/7})$
- $r = 2$ ,  $AMISE_2(h_{opt}) = O(n^{-4/9})$

To achieve a specific convergence rate for the AMISE, the sample size needs to be increase accordingly as the order  $r$  increases.

- We can also ask the question of which kernel function is optimal, and this is addressed by Muller (1984).
- His conclusion is that it is optimal to use a member of the Biweight class for a first derivative and a member of the Triweight for for a second derivative, while the Gaussian kernel is highly inefficient.
- The calculations suggest that when estimating density derivatives it is important to use the appropriate kernel.

- Let  $X \sim F$  with pdf  $f$ , since the empirical cumulative distribution function  $\hat{F}_n$  is discontinuous, our aim is at finding a continuous estimator of  $F$ .
- From the KDE of  $f$ , a direct estimator of  $F$  is

$$\hat{F}_h(x) = \int_{-\infty}^x \hat{f}_h(u) du = \frac{1}{n} \sum_{i=1}^n G\left(\frac{x - X_i}{h}\right)$$

where  $G(x) = \int_{-\infty}^x K(z) dz$ .

- Mean:

$$\begin{aligned}E[\hat{F}_h(x)] &= EG\left(\frac{x - X_1}{h}\right) \\&= h \int G(u)f(x - uh)du = - \int G(u)dF(x - uh) \\&= -G(u)F(x - uh)|_{-\infty}^{\infty} + \int F(x - uh)K(u)du \\&= \int [F(x) - uhf(x) + \frac{1}{2}h^2u^2F^{(2)}(x)]K(u)du + o(h^2) \\&= F(x) + \frac{1}{2}h^2\kappa_{21}F^{(2)}(x) + o(h^2)\end{aligned}$$

Thus, the bias of  $\hat{F}_h(x)$  is

$$bias(\hat{F}_h(x)) = \frac{1}{2}h^2\kappa_{21}F^{(2)}(x) + o(h^2)$$

- Variance: Since

$$\begin{aligned} E\left[G\left(\frac{x - X_1}{h}\right)\right]^2 &= h \int G^2(u) f(x - uh) du = - \int G^2(u) dF(x - uh) \\ &= -G^2(u)F(x - uh)|_{-\infty}^{\infty} + 2 \int F(x - uh)G(u)K(u)du \\ &= 2 \int [F(x) - uhf(x)]G(u)K(u)du + o(h) \\ &= F(x) - 2hf(x)D_1 + o(h) \end{aligned}$$

where the last step uses the fact that  $\int G(u)K(u)du = 0.5$  and  $D_1 = \int uG(u)K(u)du$ .

we have

$$\begin{aligned} \text{Var}[\hat{F}_h(x)] &= \frac{1}{n} \text{Var}\left[G\left(\frac{x - X_1}{h}\right)\right] \\ &= \frac{1}{n} E\left[G\left(\frac{x - X_1}{h}\right)\right]^2 - \frac{1}{n} \left[E G\left(\frac{x - X_1}{h}\right)\right]^2 \\ &= \frac{1}{n} [F(x) - 2hf(x)D_1] - \frac{1}{n} \left[F(x) + \frac{1}{2}h^2\kappa_{21}F^{(2)}(x)\right]^2 + o\left(\frac{h}{n}\right) \\ &= \frac{1}{n} F(x)(1 - F(x)) - \frac{2h}{n} f(x)D_1 + o\left(\frac{h}{n}\right). \end{aligned}$$

Therefore,

$$\text{MSE}[\hat{F}_h(x)] = \frac{1}{n} F(x)(1 - F(x)) + h^4 C_1(x) + \frac{h}{n} C_2(x) + o\left(\frac{h}{n} + h^4\right)$$

where  $C_1(x) = \frac{1}{4}\kappa_{21}^2 [F^{(2)}(x)]^2$ ,  $C_2(x) = -2f(x)D_1$ .

We then have the MISE:

$$\begin{aligned} MISE(h) &= \frac{1}{n} \int F(x)(1 - F(x))dx + h^4 \int C_1(x)dx + \frac{h}{n} \int C_2(x)dx \\ &\quad + o(h^4) + o\left(\frac{h}{n}\right). \end{aligned}$$

The optimal bandwidth is

$$h_{opt} = \left[ \frac{\int C_2(x)dx}{4 \int C_1(x)dx} \right]^{1/3} n^{-1/3}$$

Since  $h_{opt}$  is not applicable in practice as the unknown integrands of  $C_1$  and  $C_2$ , the optimal bandwidth is then obtained by cross-validation:

$$cv_F(h) = \frac{1}{n} \sum_{i=1}^n \int [I(X_i \leq x) - \hat{F}_h^{-i}(x)]^2 dx$$

where  $\hat{F}_h^{-i}(x)$  is the CDF kernel estimator obtained after removing  $i$ th observation.

## Adaptive KDE

- The basic definition of KDE assumes that the bandwidth  $h$  is constant for every individual kernel. A useful extension is to use a different  $h$  depending on the local density of the input data points.
- Adaptive KDE can be grouped into two categories: **balloon** estimators, and **sample point** estimators.
- The balloon estimator takes the form

$$\hat{f}_B(x; h) = \frac{1}{nh(x)} \sum_{i=1}^n K\left(\frac{x - X_i}{h(x)}\right)$$

- Unfortunately, the balloon estimator suffers from a number of drawbacks the biggest one being that this estimator does not, in general, integrate to one over the entire domain.

- The MSE criterion means that the asymptotically optimal bandwidth is

$$h_{AMSE}(x) = \left[ \frac{f(x)\|K\|^2}{\kappa_{21}^2(f''(x))^2} \right]^{1/5} n^{-1/5}$$

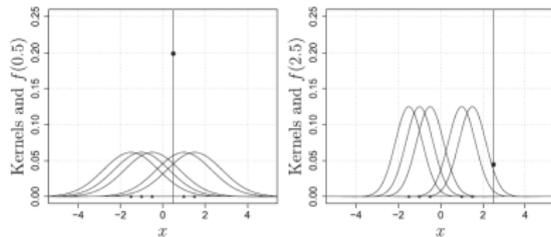

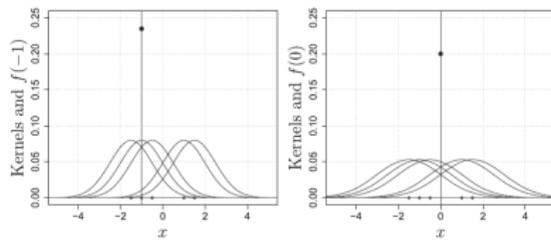

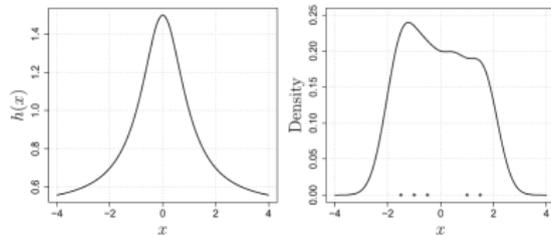

- The following Figure demonstrates how the balloon KDE works. The five data points are

$$X_1 = -1.5, X_2 = -1, X_3 = -0.5, X_4 = 1, X_5 = 1.5$$

and an arbitrary chosen bandwidth function is

$$h(x) = 0.5 + 1/(x^2 + 1).$$

The top left plot shows the  $h(x)$  function. The top right plot shows the balloon KDE  $\hat{f}_B(x; h(x))$ . The last four plots show the kernels centered at each data point  $X_i$  and the KDE estimates at points  $x = -1, x = 0, x = 0.5$  and  $x = 2.5$ . For every point  $x$ , a fixed bandwidth is chosen according to the  $h(x)$  function.

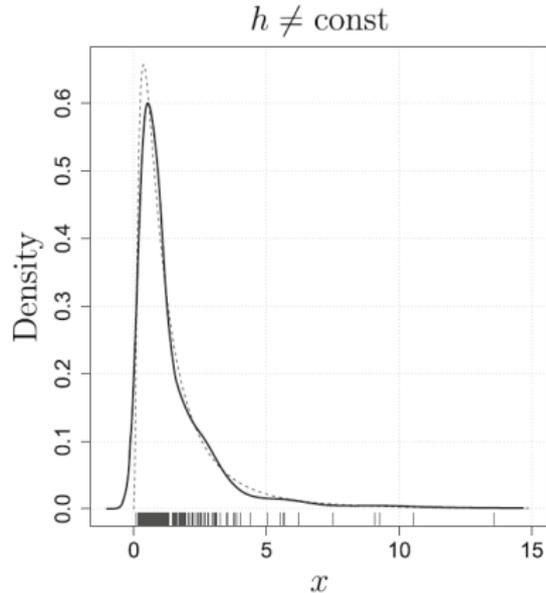

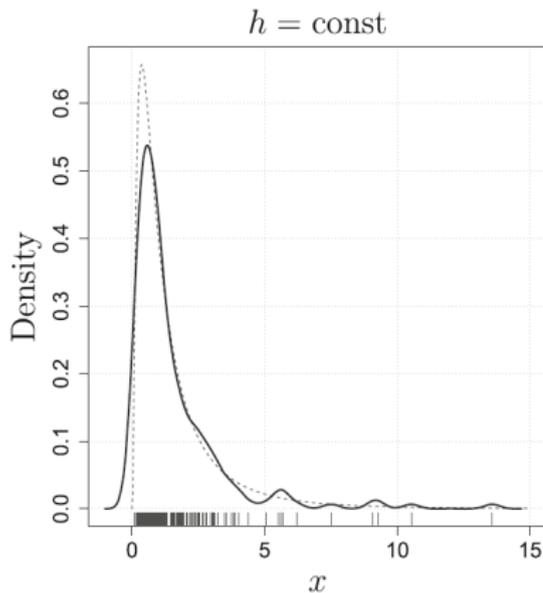

- The sample point estimator uses a different bandwidth for each data point  $X_i$ . The estimate of  $f$  at every  $x$  is then an average of differently scaled kernels centered at each data point  $X_i$ . This estimator is described in the following way

$$\hat{f}_{SP}(x; h(X_i)) = \frac{1}{n} \sum_{i=1}^n \frac{1}{h(X_i)} K\left(\frac{x - X_i}{h(X_i)}\right)$$

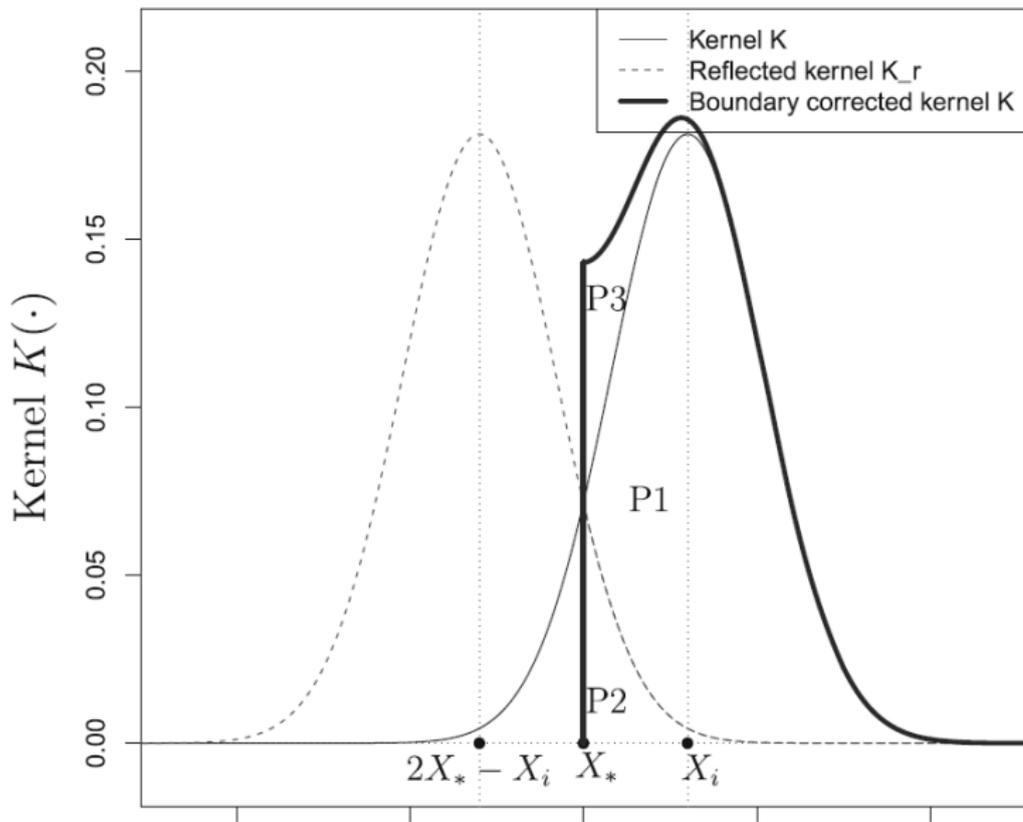

- Sample points estimators are 'true' densities but can suffer from another drawback, that is the estimate at a certain point can be strongly affected by data located far from the estimation point. However, this seems not to be a very serious problem in terms of practical applications and sample points estimators prove to be very useful.

A demonstration of the sample point KDE for the density  $N(\ln x; \mu = 0, \sigma = 1)$  with  $n = 100$  and  $h = 0.3$ . The true density is plotted in the dashed line.

## Kernel Density Estimation with Boundary Correction

- A general problem with KDE is that certain difficulties can arise at the boundaries and near them.
- In many practical situations the values of a random variable  $X$  are bounded. Even if a kernel with finite support is used, the consecutive KDE can usually go beyond the permissible domain.
- we present a smart procedure based on 'reflection' of some unnecessary KDE parts. See the following picture. Let the admissible domain be  $X \in [X_*, \infty]$ . The kernel  $K$  plotted in the thin solid line refers to a data point  $X_i$ .

Obviously, the left-side boundary corrected kernel estimator is

$$\hat{f}(x, h) = \frac{1}{nh} \sum_{i=1}^n \left[ K\left(\frac{x - X_i}{h}\right) + K\left(\frac{x - (2X_* - X_i)}{h}\right) \right] I(x \in [X_*, \infty)).$$

and the right-side one is

$$\hat{f}(x, h) = \frac{1}{nh} \sum_{i=1}^n \left[ K\left(\frac{x - X_i}{h}\right) + K\left(\frac{x - (2X_* - X_i)}{h}\right) \right] I(x \in (-\infty, X_*]).$$

## Boundary correction in general

- Assume, the support of  $f$  is  $[0, \infty)$  and that  $f$  is two times continuous differentiable.  $K$  symmetric pdf with support  $[-1, 1]$ .
- **Statistical properties in the interior of  $f(x)$ ,  $x \geq h$ :**

$$E\hat{f}_h(x) \approx f(x) + \frac{1}{2}h^2\kappa_{21}f''(x)$$

$$\text{Var}(\hat{f}_h(x)) \approx \frac{1}{nh}\kappa_{02}f(x)$$

for  $h = h(n) \rightarrow 0, n \rightarrow \infty$  and  $nh \rightarrow \infty$ .

- **Statistical properties at the boundary of  $f(x)$ ,  $x < h$ :**

Let  $x = ph$  and  $p < 1$  (For  $p \geq 1$  we are in the interior)

$$E\hat{f}_h(x) \approx a_0(p)f(x) - a_1(p)hf'(x) + \frac{1}{2}h^2a_2(p)f''(x)$$

$$\text{Var}(\hat{f}_h(x)) \approx \frac{1}{nh}b(p)f(x)$$

where  $a_l(p) = \int_{-1}^p u^l K(u)du$  and  $b(p) = \int_{-1}^p K^2(u)du$ .

Consistent: The kernel estimator is not consistent at the boundary,  
 $E\hat{f}_h(0) \rightarrow \frac{f(0)}{2}$ .

## Simple $O(h)$ boundary corrections

**Ensuring consistency at the boundary:** Ensure the leading term in the expectation of the "boundary- corrected" kernel density estimate is  $f(x)$ .

**Renormalization:**

The multiplier of  $f(x)$  is  $\int_{-1}^p K(u)du$

**Problem:** The kernel mass "lost" beyond the boundary.

**One solution:** Renormalize each kernel to integrate to 1 ("local" renormalization)

$$\hat{f}_N(x) = \frac{\hat{f}_h(x)}{a_0(p)}$$

Notice:  $a_0(p) = 1$  for  $p \geq 1$ , the formula works also in the interior.

- **Statistical properties of  $\hat{f}_N(x)$ :** For  $\hat{f}_N(x) = \frac{\hat{f}_h(x)}{a_0(p)}$ :

$$E\hat{f}_N(x) \approx f(x) - h \frac{a_1(p)}{a_0(p)} f'(x)$$

$$Var(\hat{f}_N(x)) \approx \frac{1}{nh} \frac{b(p)}{a_0^2(p)} f(x)$$

Notice:  $\hat{f}_N$  is consistent, but the bias is of order  $O(h)$  near the boundary. Optimal MSE is of order  $n^{-2/3}$  at the boundary, and of order  $n^{-4/5}$  elsewhere.

- Another solution: (**Reflection**) Reinstate the "missing mass" by reflecting the estimate in the boundary

$$\hat{f}_R(x) = \hat{f}_h(x) + \hat{f}_h(-x)$$

or equivalently replace  $K_h(x - X_i)$  by  $K_h(x - X_i) + K_h(-x - X_i)$ .

- **Statistical properties of  $\hat{f}_R(x)$ :** For  $\hat{f}_R(x) = \hat{f}_h(x) + \hat{f}_h(-x)$ :

$$E\hat{f}_R(x) \approx f(x) - 2h[a_1(p) + p(1 - a_0(p))]f'(x)$$

$$Var(\hat{f}_R(x)) \approx \frac{1}{nh}(\kappa_{02} + 2 \int_{-1}^p K(u)K(u - 2p)du)f(x)$$

Notice:  $\hat{f}_R$  is consistent, but the bias is of order  $O(h)$  near the boundary. Optimal MSE is of order  $n^{-2/3}$  at the boundary, and of order  $n^{-4/5}$  elsewhere.

## Comparison of renormalization $\hat{f}_N$ and reflection $\hat{f}_R$ :

We compare the leading terms of bias and variance as function of  $p$  (ie. multipliers of  $-hf'(x)$  and  $\frac{1}{nh}f(x)$ , respectively) for the biweight kernel,  $K(t) = \frac{15}{16}(1-x^2)^2, x \in [-1, 1]$ .

- The leading terms of bias and variance of  $\hat{f}_N$

$$B(p) = \frac{a_1(p)}{a_0(p)}, V(p) = \frac{b(p)}{a_0^2(p)}$$

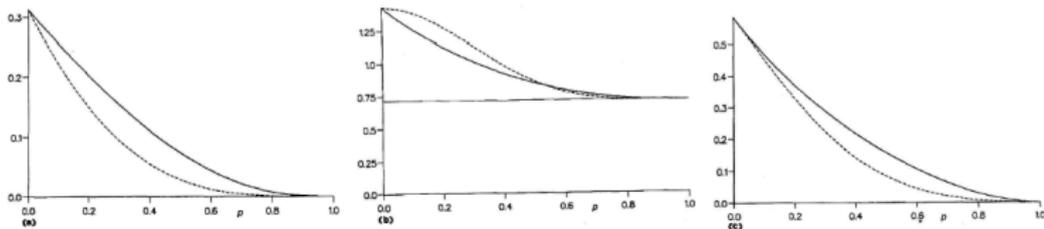

- The leading terms of bias and variance of  $\hat{f}_R$

$$B(p) = 2[a_1(p) + p(1 - a_0(p))],$$

$$V(p) = (\kappa_{02} + 2 \int_{-1}^p K(u)K(u - 2p)du)$$

- Optimized mean squared error

$$[B(p)V(p)]^{2/3}$$

$\hat{f}_N$ : Renormalization (solid line), and  $\hat{f}_R$ . Reflection (dashed line).

- Bias: Bias of  $\hat{f}_R \leq$  Bias of  $\hat{f}_N$  for  $p \in [0, 1]$  (small difference).
- Variance: Variance of  $\hat{f}_R \geq$  Variance of  $\hat{f}_N$  for  $p$  less than about one half and opposite above one half (marginally).
- Combination of variance and bias: Reflection beats renormalization for all  $p$  (but small difference).

**General conclusion:** Very little difference between the two methods, and not as good as the following methods...

## Generalized jackknifing

**Goal:**  $O(h^2)$  bias near the boundary as well as in the interior.

**Idea:** Take a linear combination of  $K$  and  $L$  (closely related to  $K$ ) in such a way that the resulting kernel has  $a_0(p) = 1$  and  $a_1(p) = 0$ . The following linear combination has the desired  $O(h^2)$  bias property

$$\frac{c_1(p)K(x) - a_1(p)L(x)}{c_1(p)a_0(p) - a_1(p)c_0(p)}$$

where  $c_l(p) = \int_{-1}^p u^l L(u) du$ .

For  $L(x) = cK(cx)$ , where  $0 < c < 1$ . Then the resulting "boundary kernel" is

$$K_c(x) = \frac{(a_1(pc) - a_1(c))K(x) - a_1(p)c^2K(cx)}{(a_1(pc) - a_1(c))a_0(p) - a_1(p)c(a_0(pc) + a_0(c) - 1)}$$

Choose  $c = c(K)$  to optimize eg. some measure of effectiveness of the kernel, however there is very little to be gained.

Instead, let  $c \rightarrow 1$ ,

$$K_{PD}(x) = \frac{a_2^{(1)}(p)K(x) - a_1(p)xK'(x)}{a_2^{(1)}(p)a_0(p) - a_1(p)a_1^{(1)}(p)}$$

where  $a_l^{(1)} = \int_{-1}^p x^l K'(x) dx$

Notice: Alternative derivation would be to seek the appropriate linear combination of  $K(x)$  and  $xK'(x)$  to use as a boundary kernel.

A particularly useful boundary kernel comes from the linear combination of  $K(x)$  and  $xK(x)$

$$K_L(x) = \frac{a_2(p)K(x) - a_1(p)xK(x)}{a_0(p)a_2(p) - a_1^2(p)}$$

Another boundary kernel

$$K_D(x) = \frac{a_1^{(1)}(p)K(x) - a_1(p)K'(x)}{a_1^{(1)}(p)a_0(p) - a_1(p)a_0^{(1)}(p)}$$

which is a linear combination of  $K(x)$  and  $K'(x)$ .

Notice:  $K_D$  not applicable to the uniform kernel, and  $K_D$  analogous to  $K_L$  for the normal kernel.

- Extension of reflection

$$K_{R1}(x) = \frac{(2p(1 - a_0(p)) + a_1(p))K(x) - a_1(p)K(2p - x)}{(2p(1 - a_0(p)) + a_1(p))a_0(p) - a_1(p)(1 - a_0(p))}$$

## Overview of boundary kernels

- General Jackknifing:

$$\frac{c_1(p)K(x) - a_1(p)L(x)}{c_1(p)a_0(p) - a_1(p)c_0(p)}$$

- Comb. of  $K(x)$  and  $cK(cx)$ :

$$K_c(x) = \frac{(a_1(pc) - a_1(c))K(x) - a_1(p)c^2K(cx)}{(a_1(pc) - a_1(c))a_0(p) - a_1(p)c(a_0(pc) + a_0(c) - 1)}$$

- Comb. of  $K(x)$  and  $cK(cx)$  for  $c \rightarrow 1$  (comb. of  $K(x)$  and  $xK'(x)$ ):

$$K_{PD}(x) = \frac{a_2^{(1)}(p)K(x) - a_1(p)xK'(x)}{a_2^{(1)}(p)a_0(p) - a_1(p)a_1^{(1)}(p)}$$

- Comb. of  $K(x)$  and  $xK(x)$ :

$$K_L(x) = \frac{a_2(p)K(x) - a_1(p)xK(x)}{a_0(p)a_2(p) - a_1^2(p)}$$

- Comb. of  $K(x)$  and  $K'(x)$  (ext. of renormalization):

$$K_D(x) = \frac{a_1^{(1)}(p)K(x) - a_1(p)K'(x)}{a_1^{(1)}(p)a_0(p) - a_1(p)a_0^{(1)}(p)}$$

- Comb. of  $K(x)$  and  $K(2p-x)$  (ext. of reflection):

$$K_{R1}(x) = \frac{(2p(1 - a_0(p)) + a_1(p))K(x) - a_1(p)K(2p - x)}{(2p(1 - a_0(p)) + a_1(p))a_0(p) - a_1(p)(1 - a_0(p))}$$

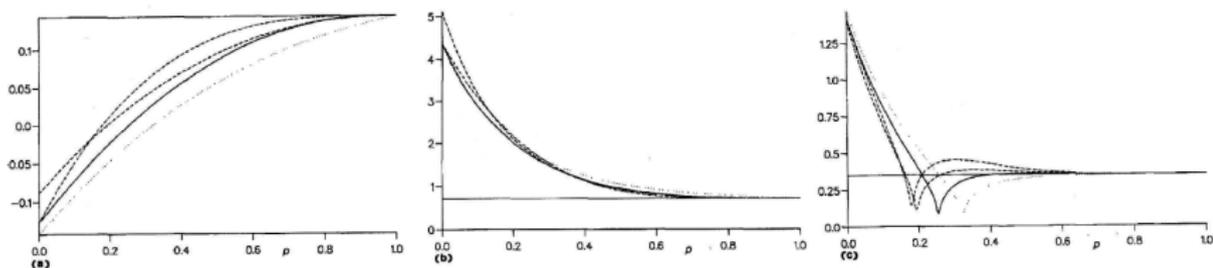

### Comparison of $O(h^2)$ boundary kernels:

Compare the leading coefficients of bias and variance (ie. the multiplier of  $\frac{1}{2}h^2 f''(x)$  and  $\frac{1}{nh} f(x)$ , respectively).

General formulae in terms of  $K$  and  $L$  for all generalized jackknife boundary kernels

$$B(p) = \frac{c_1(p)a_2(p) - a_1(p)c_2(p)}{c_1(p)a_0(p) - a_1(p)c_0(p)}$$
$$V(p) = \frac{c_1^2(p)b(p) - 2c_1(p)a_1(p)e(p) + a_1^2(p)g(p)}{(c_1(p)a_0(p) - a_1(p)c_0(p))^2}$$

where  $e(p) = \int_{-1}^p K(x)L(x)dx$  and  $g(p) = \int_{-1}^p L^2(x)dx$ .

Bias, variance and optimized MSE for  $K_{PD}$  (dotted line),  $K_L$  (dashed line),  $K_D$  (solid line) and  $K_{R1}$  (dot-dashed line).

- Bias: Bias curves same shape and range of values. Each curve has a single point where it crosses zero.
- Variance: The variance is very similar.
- Optimized MSE:  $\{B(p)V^2(p)\}^{2/5}$ . Similar curves.

Note: The slightly increased variance of  $\hat{f}_L$  close to  $p=0$  is balanced by the better bias there (dashed line).

## general conclusion

- Almost equivalent results for all generalized jackknives.
- Major problem: The variance at (and very close to)  $p = 0$ .

For the biweight kernel

$$\frac{V(\hat{f}_L(0))}{V(\hat{f}_L(1))} \approx 7.16$$

whereas

$$\frac{V(\hat{f}_N(0))}{V(\hat{f}_N(1))} \approx 2$$

Hope for improved boundary corrections techniques. Local linear estimation has an attractive performance at the boundaries. (see reading paper for details)

## Higher-order kernels

- We know that the best obtainable rate of convergence of the kernel estimator is of order  $n^{-4/5}$ . If we loose the condition that  $K$  must be a density, the convergence rate could be faster.
- We say an asymmetric function  $K$  is a  $k$ th order kernel if

$$\int K(u)du = 1, \int u^j K(u)du = 0 \text{ for } j = 1, \dots, k - 1$$

and

$$\int u^k K(u)du \neq 0$$

- Note that we do not require that  $K(u) \geq 0$ .
- One way to generate higher-order kernels is deductively from the lower-order kernels,

$$K_{[k+2]}(u) = \frac{3}{2}K_{[k]}(u) + \frac{1}{2}uK'_{[k]}(u)$$

for example, set  $K_{[2]}(u) = \phi(u)$ , then

$$K_{[4]}(u) = \frac{1}{2}(3 - u^2)\phi(u).$$

- Another way is developed when  $f$  is a normal mixture density for a certain class of higher-order kernels

$$G_{[k]}(u) = \sum_{l=0}^{k/2-1} \frac{(-1)^l}{2^l l!} \phi^{(2l)}(u), l = 0, 2, 4, \dots$$

For example, recall the asymptotic bias is given by

$$E\hat{f}_h(x) - f(x) = \frac{h^2}{2}\kappa_{21}f''(x) + o(h^2)$$

If we use 4th order kernel, then

$$\begin{aligned} E\hat{f}_h(x) &= \frac{1}{h} \int K\left(\frac{z-x}{h}\right)f(z)dz = \int K(u)f(x+uh)du \\ &= \int K(u)[f(x) + f'(x)uh + \frac{1}{2}f''(x)u^2h^2 + \frac{1}{3!}f^{(3)}(x)u^3h^3 \\ &\quad + \frac{1}{4!}f^{(4)}(x)u^4h^4 + o(h^4)]du \\ &= f(x) + \frac{1}{4!}f^{(4)}(x)\kappa_{41}h^4 + o(h^4) \end{aligned}$$

The variance does not change, that is,

$$Var(\hat{f}_h(x)) = \frac{f(x)}{nh}\kappa_{02} + o\left(\frac{1}{nh}\right)$$

Therefore,

$$AMISE(h) = \frac{\kappa_{02}}{nh} + \frac{1}{(4!)^2} \|f^{(4)}\|^2 \kappa_{41}^2 h^8$$

Then the optimal bandwidth is

$$h_0 = \left[ \frac{72\kappa_{02}}{\|f^{(4)}\|^2 \kappa_{41}^2} \right]^{-1/9} n^{-1/9}$$

and  $AMISE(h_0)$  thus has an optimal convergence rate of order  $O_p(n^{-8/9})$ .

- The convergence rate can be made arbitrarily close to the parametric  $n^{-1}$  as the order increases, which means it will eventually dominate second-order kernel estimators for large  $n$ . However, it does need a larger sample size ( $K_{[4]}$  would require several thousand in order to reduce MISE compared to normal kernel).
- Another price that need to be paid for higher-order kernels is the negative contributions of the kernel may make the the estimated density not a density itself.

- CRAN packages **graphics::hist** and **ash** packages allows users to generate a histogram of the data  $x$ .
- CRAN packages **GenKern**, **kerdiest**, **KernSmooth**, **ks**, **np**, **plugdensity**, and **sm** all use the kernel density approach, as does **stats::density**. They differ primarily in their means of selecting bandwidth.
- CRAN packages **vemix** provides density, cumulative distribution function, quantile function and random number generation for boundary corrected kernel density estimators using a variety of approaches.

Package	Function call	Max Dim.	Arbitrary Grid	Predicted Density	Approach
<b>ASH</b>	ash1(bin1(x, ab = c(min(x), max(x)), nbin = 512))	2	No	d\$y	ASH
<b>ftnonpar</b>	pmden(x)	1	No	d\$y	Taut Strings
<b>GenKern</b>	KernSec(x, 512, range.x = c(min(x), max(x)))	2	No	d\$yden/100	Kernel
<b>gss</b>	dssden(ssden(~x), seq(min(x), max(x), length = 512))	2	Yes	d	Penalized
<b>kerdiest</b>	kerdiest::kde(vec.data = x, y = xgrid)	1	Yes	d\$Estimated_values	Kernel
<b>KernSmooth</b>	bkde(x = x, gridsize = 512L, range.x(min(x), max(x)))	2d	No	d\$y	Kernel
<b>ks</b>	kde(x = x, hpi(x), eval.points = xgrid)	6	Yes	d\$estimate	Kernel
<b>loefit</b>	density.lf(x, ev = xgrid)	1	Yes	d\$y	Local Likelihood
<b>logspline</b>	dlogspline(xgrid, logspline(x))	1	Yes	d	Penalized
<b>MASS</b>	hist(x, 512)	1	Yes	d\$density	Histogram
<b>np</b>	npudens(~ x, edat = xgrid)	1	Yes	d\$dens	Kernel
<b>pendensity</b>	pendensity(x ~ 1)	1	No	d\$results\$fitted	Penalized
<b>plugdensity</b>	plugin.density(x, xout = xgrid)	1	Yes	d\$y	Kernel
<b>stat</b>	density(x, n = 512)	1	No	d\$y	Kernel
<b>sm</b>	sm.density(x, display = "none", eval.points = xgrid)	3	Yes	d\$estimate	Kernel

Table 1: Packages we investigated. We assume that the estimate output is  $\mathbf{d}$ , the input data is  $\mathbf{x}$ , and the desired evaluation grid is  $\mathbf{xgrid}$ , which sequences  $x$  into 512 evaluation points.
